**PRIORITY
DOCUMENT**

SUBMITTED OR TRANSMITTED IN
COMPLIANCE WITH RULE 17.1(a) OR (b)

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 01645 500505
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

TRANSFERRING MATERIALS INTO CELLS AND A MICRONEEDLE ARRAY

This invention relates to ways of transferring materials into cells,
5 and also to a microneedle array.

There are many times when it is necessary to transfer materials into
cells, for example nucleic acids or nucleic acid constructs, such as vectors
or plasmids, etc. have to be transferred into a cell for the purposes of
10 genetic manipulation. Furthermore, chemicals may also need to be
transferred into cells, e.g. nucleotides or stains, and chemicals to affect
the physiology of a cell. A number of chemical and mechanical processes
have been developed to convey materials into cells. These techniques
include:-

- 15 1. direct microinjection - a needle is inserted into a cell and material
expelled through the needle;
2. electroporation - the cell membrane is made permeable to some
molecules by application of a high voltage shock;
- 20 3. biolistics - tungsten or gold particles are coated with the substance
desired to be introduced and are shot into the cell;
4. calcium phosphate co-precipitation - cells absorb calcium
25 phosphate, and if DNA/other material co-precipitates with the
calcium phosphate it is also taken into the cell;
5. mediated transformation (via liposome, viral, or bacterial vectors);
and

6. protoplast transformation.

An aim of one aspect of the present invention is to use a new material to assist in the transfer of substances to cells.

5

An aim of another aspect of the invention is to provide an improved way of providing small volumes of a substance.

Direct microinjection involves the insertion by a microneedle of DNA directly into the nucleus of individual cells. A glass micropipette linked to a micromanipulator is used to inject 10^{-8} - 10^{-7} μ l typically a solution of DNA fragments into cell nuclei. "Hits" are almost certain, given considerable operator expertise but the technique is laborious and cannot be applied to a large number of cells.

15

According to a first aspect the invention comprises a cell-penetrating member made of porous silicon.

The cell-penetrating member is adapted to have a substance to be introduced into a cell carried by the porous silicon.

It has been discovered that porous silicon is biocompatible, and it has now been discovered that porous silicon can be corroded in, or resorbed into, a mammalian body without significant detrimental effect. Porous silicon can be used to locate and mount biological material (or any substance to be introduced into a cell).

It is known from PCT Patent Application No. PCT/US95/12381 to have an array of micromachined bulk silicon barbs or tips and to use them mechanically to pierce the plasma membrane of large numbers of cells

simultaneously. This is more efficient than piercing a single cell with a single needle, which can result in a laborious operation if hundreds of cells need to have material introduced into them. The tips of PCT/US95/1281 are, with hindsight, less effective at transferring material (e.g. DNA) into a pierced cell than they might be. It is, for example, proposed in that document to use surface tension forces between closely-spaced tips to hold biological material to be introduced into the cells in the spaces between the tips, and to trap it between the tips (probes) and the substrate.

10

According to a second aspect, the invention comprises a micropiercer comprising at least a region of porous silicon.

The porous silicon region is adapted to immobilise a substance (e.g. DNA). The porous silicon region is preferably at the tip of the micropiercer. The micropiercer may be a tip or barb, with no central lumen, or it may be a needle with a central channel. The micropiercer may have a pore network extending from a reservoir or channel to a substance delivery region provided on the surface of the micropiercer.

20

The micropiercer may have a coating of porous silicon, or it may be porous throughout its cross-section, at least at its tip (or other substance delivery region if that is not the tip). Substantially the whole exterior surface of the micropiercer that penetrates a cell in use may comprise porous silicon. The micropiercer may be a bulk silicon microtip with a porous silicon coating.

25

An advantage of holding the substance to be introduced to the cell at the tip of the micropiercer itself, instead of in channels/spaces between tips, is that the material is definitely introduced into the cell, and

30

typically deeply into the cell. This may increase the success rate of the operation (in many cases introducing DNA into cells and stable uptake of the DNA/fragment is not statistically very successful - a few percent may succeed, which is why so many cells have to be injected).

5

Instead of using porous silicon to immobilise the material on the tip/ensure at least some material is present on the tip, other holding means may be used. For example, polycrystalline silicon can hold some substances at grain boundaries. The holding means may comprise a porous material.

10

It is known to immobilise DNA fragments in macroporous silicon in the field of a flow-through genosensor (Advances in Genosensor Research. K.L. Beattie et al. Clin. Chem. 41, 700 (1995)).

15

An advantage of porous silicon is that its bioactivity can be tuned by controlling its pore size and porosity. It is therefore possible to create a micropiercer with a porous tip with pores tailored to hold/immobilise a particular desired molecule or substance. Of course, the substance will not be so immobilised that at least some of the material cannot leave the tip when the tip is in the cell.

20

Porous silicon has another great advantage as the choice of material for a micropiercer in that micromachining techniques for fabricating small scale devices from silicon exist, e.g. in the electronics industry.

25

It is known how to make a silicon structure porous (see for example US 5 348 618, the contents of which are hereby incorporated by reference).

30

An array of micropiercers may be provided.

It is also known to have an array of microtips for a completely different purpose - for field emission cathodes used in vacuum microelectronic applications. Here, a 5mm square silicon chip will typically contain about 500 microtips of pyramidal shape with tip widths of 50nm - 1 μ m and heights of 10 - 100 μ m, depending upon the manufacturing parameters chosen. With hindsight, these would be suitable for porosification and then use as micropiercers for transferring a substance into cells. It is also even known to have porous silicon pyramidal cathodes - e.g. Field emission from pyramidal cathodes covered in porous silicon. P.R. Wilshaw et al. J. Vac. Sci. Techn. B12,1 (1994); Fabrication of Si field emitters by forming porous silicon. D. Kim et al. J. Vac. Sci. Tech. B14, 1906 (1996); and Porous silicon field emission cathode development. J.R. Jessing et al. J. Vac. Sci. Techn. B14, 1899 (1996). However, these are all in a totally different field, and none show a micropiercer having held on it DNA, RNA, or any other substance to be introduced into a cell.

According to a third aspect, the invention comprises a method of producing a micropiercer device comprising manufacturing one or more micropiercer projections, and providing substance holding means at or near the tip of the projections.

Preferably the method comprises making at least a part of the projections porous. Preferably the method comprises making the tip of the projection porous, or providing a porous coating on the tip. Preferably the tip is made porous using an HF anodising technique.

According to another aspect, the invention comprises a method of transferring a material into a cell comprising associating the material with a tip portion of a micropiercer and piercing the cell with the micropiercer.

- 5 Preferably the method comprises using porous silicon to locate the material at or near the tip portion.

- According to a further aspect, the invention comprises a method of genetic manipulation of a cell comprising associating genetic material with
10 a tip portion of a micropiercer, piercing the cell with the micropiercer to allow the genetic material to enter the cell. The genetic material may then be stably incorporated in the cell.

- According to another aspect, the invention comprises a microneedle
15 array comprising a plurality of needles extending away from a support, the needles each having fluid transport means adapted to transport fluid from their bases to their tips, and fluid supply means communicating with the fluid transport means and adapted to supply fluid to be injected to the base of the needles.

20

 Preferably the array of microneedles are made of silicon. It may be micromachined, for example from a silicon wafer.

- The fluid transport means may comprise a reservoir, which may
25 extend under the needles. The device may comprise a body having a lower portion, an upper portion, and a channel or reservoir extending between the upper and lower portions, with the needles being provided in the upper portion and the fluid transport means extending to the reservoir or channel.

30

The fluid transport means may comprise a single lumen, or macropore in each needle which may extend generally centrally of the needle. Alternatively, or additionally, the fluid transport means may comprise a pore or capillary network, such as a plurality of mesopores.

5

The array of needles may be provided on an integrated silicon chip, which may also have a sensor provided on it, the sensor preferably enabling one to monitor in situ the transfection process. For example a photo emitter/detector may be used in association with light emitting markers (e.g. fluorescent) associated with the DNA. It may also be desirable to have a power supply and/or processing circuitry, and/or control circuitry provided on the chip. Arrays of light emitting devices and photodetectors may enable the transfection process to be monitored under high spacial resolution.

15

According to another aspect, the invention comprises a method of manufacturing a microneedle, or a microneedle array, the method comprising taking a bulk silicon wafer and creating a needle or an array of needles; and creating fluid transfer means extending from the base of the or each needle to its tip.

20

Preferably, the method comprises providing a network of pores from the base of the or each needle to its tip. The pores may be macropores or mesopores, or for some applications they may even be micropores (but macropores are preferred).

25

The or each needle may be created using photolithographic techniques such as anisotropic etching and photo-resist lithographic techniques.

30

The silicon substrate may be an n-type substrate with a resistivity in the range of 0.1-10 Ω cm.

5 The in-filled and planarised array may then be treated so as to expose just the tips, for example by using an oxygen plasma treatment and an HF dip to expose the tips alone. The tips can then be anodised to create the macropores from the tip to the wafer back surface. The wafer, provided with an array of tips, may then be bonded to another backing member, which may be shaped so as to define a channel or reservoir
10 between the tip-carrying wafer and the backing member.

According to a further aspect the invention comprises a vehicle for transferring material into a cell, the vehicle comprising at least in part resorbable material.
15

Preferably the vehicle comprises resorbable silicon, such as porous silicon, or polycrystalline silicon. The whole of the vehicle may be made of the resorbable material, or only part of it. The vehicle may comprise bioactive silicon. (By "resorbable" it is meant that the material is
20 corroded/absorbed/eroded/ or otherwise disappears when in situ in physiological fluids. By "bioactive" it is meant that the material can induce the deposition of calcium phosphate precipitates on its surface under physiological conditions (when in body fluids).

25 If the vehicle is retained in the cell it will be adsorbed/corroded/eroded or resorbed, or partially resorbed, and be less of an irritation/foreign body to the cell in due course.

The resorbable silicon/other material may be used in a biolistics
30 technique.

The vehicle for transferring material into the cell may comprise a biolistic bullet comprising porous silicon.

5 The bullet may have a substance to be introduced into a cell adhered to it. The bullet may be impregnated with material (e.g. DNA material). It may be substantially saturated with material. The bullet may comprise a submicron silicon particle. The silicon particle may be rendered porous by stain etching techniques. The particle is preferably
10 mesoporous.

A resorbable biolistic bullet would not leave behind in the cell a particle, as do gold or tungsten biolistic bullets. The bullet need not be porous all of the way through - it may have a porous coating. The
15 resorbable bullet need not necessarily be made of porous silicon, or of silicon at all, but porous silicon has been identified as an especially suitable material.

According to another aspect, the invention provides a method of
20 transferring material into a cell comprising the steps of shooting a vehicle carrying said material into the cell.

Preferably the vehicle is the vehicle as hereinabove defined. Preferably the bullet is shot into the cell by means of a pressurised gas,
25 for example helium.

The process of biological biolistics is often used where more standard techniques do not work. Resorbable impregnated materials, such as porous silicon offer biocompatible advantages over corrosion-resistant
30 bulk metal materials.

According to a further aspect the present invention provides a method of making a vehicle for transferring material into a cell comprising the steps of rendering the vehicle at least partially porous and
5 introducing to the vehicle the material to be transferred to the cell.

Preferably the vehicle comprises a silicon bullet, most preferably a submicron silicon particle, which may be rendered porous, preferably mesoporous by stain etching techniques. The bullet may have the material
10 to be introduced to the cell adhered to it or alternatively it may be impregnated with the material.

The vehicle for transferring material into a cell may comprise bioactive silicon. It may comprise a bioactive silicon particle having the
15 material to be transferred in a form adapted to co-precipitate with a substance which is taken up by cells. The co-precipitate may be a calcium phosphate precipitate.

According to another aspect the invention comprises a method of
20 introducing material into a cell comprising associating the material with a silicon particle, precipitating calcium phosphate onto the particle to form a calcium phosphate/silicon particle combined particle, and arranging for the cell to uptake the calcium phosphate/silicon particle combination.

25 In the technique of electroporation the cell membrane can be made permeable by exposing cells to a brief electric shock of very high voltage. Low porosity bioactive silicon is electrically conducting and is suitably developed as an intimate coupling matrix for adherent mammalian cells growing on microelectrode arrays.

By having bioactive silicon, e.g. porous silicon or polycrystalline silicon, as one or both electrodes in electroporation apparatus it is envisaged that better DNA transfer takes place.

5 According to a further aspect the invention comprises a method of electroporation comprising providing an electrically conducting bioactive silicon electrode.

 Preferably the method comprises growing cells on the electrode.
10 The method may comprise providing an array of bioactive silicon electrodes, possibly with cells grown on them. The electrode, or electrodes, may be coated with porous silicon or may be of porous silicon throughout their cross-section, at least at a region of their height.

15 According to a further aspect the invention comprises electroporation apparatus comprising a bioactive electrode. Preferably the electrode is bioactive silicon, most preferably porous silicon. An array of electrodes, or microelectrodes, may be provided.

20 The invention may also reside in the use of bioactive silicon, preferably porous silicon, in the preparation of apparatus for the introduction of materials into cells.

 Several embodiments of the present invention will now be
25 described by means of example only with reference to the Figures, in which:-

 Figure 1 shows a partially porosified silicon microtip;

30 Figure 2 shows a silicon microneedle array;

Figure 3 shows the silicon microneedle array of Figure 2 having a macroporous network running from the tip to an underlying reservoir;

5

Figure 4 shows a porous silicon bullet impregnated with DNA;

Figure 5 shows a porous silicon core impregnated with DNA and surrounded by calcium phosphate; and

10

Figure 6 illustrates the electroporation technique of the present invention.

Figure 1 shows a micropiercer 10 in the form of a microtip 12 having a base width A of $50\mu\text{m}$ and a height B of $100\mu\text{m}$ and a tip width C of $0.5\mu\text{m}$. The surface of the microtip 12 is coated with porous silicon 14 having a depth D of $0.1\mu\text{m}$.

In use, the porous silicon coating 14 immobilises the substance to be delivered to the cell (e.g. DNA/RNA) on the tip itself, which increases the chances of the immobilised substance on the tip being introduced into the cell.

The pore size and porosity of the porous silicon coating can be controlled to tune the bioactivity of the microtip 12. By controlling the pore size and porosity of the porous silicon, we can make particular molecules come off it more, or less, readily. We may leave the microtips inside a cell for a predetermined time to allow molecules to disassociate themselves from the porous silicon.

30

Figure 2 shows an array 20 of silicon microneedles 22 extending away from a silicon support, or back, member 24. The microneedles 22 have porous silicon microtips 26 and a central lumen 28 communicating between the microtips 26 and a reservoir 30 defined between an upper member 32, provided with the microneedles 22 and the back, support, member 24. The back member 24 is of bulk silicon.

Figure 3 shows an array 33 of silicon microneedles 34 that is similar to that of Figure 2. The principal difference between the arrays shown in Figures 2 and 3 is that the microneedles 34 shown in Figure 3 are not provided with a central lumen 28. Instead the array 33 of silicon microneedles 34 in Figure 3 is provided with a mesoporous network 36 which extends from the microtips of the microneedles to the reservoir 30', allowing fluid communication between the reservoir 30' and the microtips.

In use, the substance to be delivered to cells is provided to the porous silicon microtips 22,34 from the reservoir 30,30' through the central lumens 28 or the mesoporous network 36. The substance is then held by the porous silicon microtips ready for introduction into a cell.

The material to be introduced into the cells may be pumped into the reservoir 30, 30', and out through the lumens 28 or porous network by a pump, not shown (but arrow 39 indicates the pump delivering liquid to the reservoir).

All or part of the silicon surfaces within the final structure may be treated in such a way as to modify their interaction with biological systems. This might be achieved by forming a layer of porous silicon on the surface. Such a layer could be formed by either an electrochemical

anodisation process or possibly by immersing the structure into a stain etching solution such as a mixture of hydrofluoric acid and nitric acid.

Figure 4 shows a biolistic bullet 40 comprising a submicron silicon particle rendered mesoporous by stain etching.

In use, the bullet 40 is impregnated with the substance to be introduced into a cell and is shot into the cell using pressurised helium. As the porous silicon is a resorbable material, it will be preferably fully resorbed, and at least partially resorbed, by the cell that it entered, and thus comprises less of a foreign body than known biolistic bullets such as gold or tungsten which leave particles of metal in the cell.

Figure 5 shows a porous silicon core 50 impregnated with a substance to be introduced into a cell (e.g. DNA/RNA) and calcium phosphate precipitate 52 formed around the core 50. The calcium phosphate 52 is co-precipitated with DNA/RNA, so that a genetic material/calcium phosphate layer surrounds the bioactive silicon core 50. The bioactive silicon core locally induces calcium phosphate supersaturation. It may be possible to place a bioactive silicon core next to a cell/against the wall of a cell, and co-precipitate DNA/ $\text{Ca}(\text{PO}_4)_2$ against the core and against the wall of the cell. If the core is phagocytosed it can be resorbed.

The core 50 need not have DNA/RNA/any active substance on it - it may simply serve as a good nucleation site for co-precipitation of DNA/ $\text{Ca}(\text{PO}_4)_2$.

It is known to use glass beads as a nucleation site for calcium phosphate co-precipitation DNA transfection - see for example the paper

by Watson and Latchman in "Methods (San Diego) 1996 10(3), 289-291 (Eng).

It will be appreciated that micropores are pores with a diameter
5 of 2 nm or less; mesopores have a diameter of 2nm - 50 nm; and
macropores have a diameter of 50 nm or more.

It has also been realised that it is possible to improve the efficiency
of the introduction of materials to cells in an electroporation technique, as
10 shown in Figure 6, using porous silicon, preferably mesoporous silicon
(but macroporous and microporous silicon are also useful).

The use of a porous silicon (or porous other bioactive material, or
bioactive polycrystalline silicon) electrode 60,61 achieves better
15 performance in electroporation. Because the electrode is bioactive,
instead of being bioinert, cells (typically animal cells) have an affinity to
it and are localised on its surface.

Low porosity (50% or less, or 30% or less, or 10% or less)
20 bioactive silicon is electrically conducting and is a suitable intimate
complex matrix for adherent mammalian cells 62, which may grow on a
microelectrode array 60,61. Thus, it is possible to grow mammalian cells
on bioactive porous silicon electrodes and then introduce DNA (or other
substances) into the cells by using electroporation, with the substrate upon
25 which the cells are grown being an electrode, or even both
electrodes 60,61, of the electroporation apparatus. This has advantages in
handling the cells, and achieves a better efficiency rate of DNA
introduction than solely having the cells suspended in a liquid medium 63.

The fact that porous silicon is resorbable/erodable in vivo in mammals has been proved by the inventors, and this underpins some aspects of the invention. The fact that silicon can be made bioactive underpins other aspects of the invention.

CLAIMS

1. A method of manufacturing a microneedle, or a microneedle array, the method comprising taking bulk silicon and creating a needle or an
5 array of needles; and creating fluid transfer means extending from the base of the or each needle to its tip.
2. The method of claim 1 further comprising providing a network of pores from the base of the or each needle to its tip.
- 10 3. The method of claim 2 wherein the pores are macropores.
4. The method of claim 2 wherein the pores are mesopores.
- 15 5. The method of claim 2 wherein the pores are micropores.
6. The method of any preceding claim wherein the or each needle is created using photolithographic techniques.
- 20 7. The method of claim 6 wherein the photolithographic technique is anisotropic etching.
8. The method of claim 6 or claim 7 wherein the photolithographic technique is a photoresistant lithographic technique.
- 25 9. The method of any preceding claim wherein the bulk silicon wafer is an n-type substrate with a resistivity in the range of 0.1-10 Ω cm.
10. The method of any preceding claim wherein the needle or needle
30 array is planarised.

11. The method of claim 10 wherein a non-conducting mask is used to planarise the needle or array of needles.

5 12. The method of claims 10 and 11 wherein the planarised needle or array is treated so as to expose just the tips.

13. The method of claim 12 wherein the treatment uses an oxygen plasma treatment and an HF dip.

10

14. The method of any one of claims 10 to 13 wherein the tips are anodised to create pores from the tip to a wafer back surface.

15. The method of any preceding claim wherein a wafer provided with an array of tips is bonded to a backing member.

15

16. The method of claim 15 wherein the backing member and/or tip-carrying wafer is shaped so as to define a channel or reservoir between the tip-carrying wafer and the backing member.

20

17. A method of producing a micropiercer device comprising manufacturing one or more micropiercer projections, and providing substance holding means at or near the tip of the projections.

25 18. The method of claim 17 further comprising making at least a part of the projections porous.

19. The method of claims 17 or 18 further comprising making the tip of the projections porous.

30

20. The method of any one of claims 17 to 19 further comprising providing a porous coating on the tip.
21. The method of any one of claims 18 to 20 wherein the tip is made
5 porous using an HF anodising technique.
22. The method of claim 18 comprising making substantially the entire extent of the tips porous.
- 10 23. A method of transferring a material into a cell comprising associating the material with a tip portion of a micropiercer and piercing the cell with the micropiercer.
24. The method of claim 23 further comprising using porous silicon to
15 locate the material at or near the tip portion.
25. A method of genetic manipulation of a cell comprising associating genetic material with a tip portion of a micropiercer and piercing the cell with the micropiercer to allow the genetic material to enter the cell.
- 20 26. A microneedle array comprising a plurality of needles extending away from a support, the needles each having fluid transport means adapted to transport fluid from their bases to their tips, and fluid supply means communicating with the fluid transport means and adapted to
25 supply fluid to be injected to the base of the needles.
27. The array of claim 26 wherein the microneedles are made of silicon.
- 30 28. The array of claims 26 or 27 wherein the array is micromachined.

29. The array of claim 28 wherein the array is micromachined from a silicon wafer.

5 30. The array of any one of claims 26-29 wherein the fluid transport means comprises a reservoir.

31. The array of claim 30 wherein the reservoir extends under the needles.

10

32. The array of any one of claims 26 to 31 wherein the support has a lower portion, an upper portion, and a channel or reservoir extending between the upper and lower portions, with the needles being provided in the upper portion and the fluid transport means extending to the reservoir or channel.

15

33. The array of any one of claims 26 to 32 wherein the fluid transport means comprises a porous or capillary network provided in each needle.

20 34. The array of any one of claims 26 to 32 wherein each needle has a lumen extending through its longitudinal extent.

35. The method of claim 34 wherein the network comprises a plurality of mesopores.

25

36. The array of any one of claims 26 to 35 which is provided on an integrated silicon chip.

30 37. A cell-penetrating member, or micropiercer, made of porous silicon.

38. The cell-penetrating member of claim 37 wherein the member is adapted to have a substance to be introduced into a cell carried by the porous silicon.

5

39. The cell-penetrating member of claims 37 or 38 wherein the porous silicon region immobilises a substance in comparison with its mobility when provided a bioinert substance such as titanium.

10 40. The cell-penetrating member of claims 38 or 39 wherein the porous silicon region is at the tip of the member.

41. The cell-penetrating member of claims 38 to 40 which has a tip or barb with no single central lumen.

15

42. The cell-penetrating member of claims 38 to 40 which has a needle with a central channel.

20 43. The cell-penetrating member of any one of claims 38 to 42 further having a pore network extending from a reservoir or channel to a substance delivery region provided on the surface of the micropiercer.

44. The cell-penetrating member of any one of claims 38 to 43 having a coating of porous silicon.

25

45. The cell-penetrating member of any one of claims 38 to 43 which is porous throughout its cross-section, at least at its tip.

30 46. The cell-penetrating member of any one of claims 38 to 45 which comprises a bulk silicon microtip with a porous silicon coating.

47. A vehicle for transferring material into a cell, the vehicle comprising at least, in part, resorbable material.

5 48. The vehicle of claim 47 wherein the vehicle comprises resorbable silicon.

49. The vehicle of claims 47 or 48 wherein the resorbable material is porous silicon.

10

50. The vehicle of claims 47 or 48 wherein the resorbable material is polycrystalline silicon.

51. The vehicle of claims 47 to 50 wherein the whole of the vehicle is
15 made of the resorbable material, or only part of it.

52. The vehicle of claims 47 to 51 which comprises a biolistic bullet.

53. The vehicle of claim 52 wherein the bullet has a material to be
20 introduced into a cell adhered to it.

54. The vehicle of claim 52 wherein the bullet is impregnated with material to be introduced into a cell.

25 55. The vehicle of claim 53 or 54 which is substantially saturated with material.

56. The vehicle of any one of claims 51 to 55 wherein the bullet comprises a submicron silicon particle.

30

57. The vehicle of claims 52 to 56 wherein the bullet has a porous coating.

58. The vehicle of any one of claims 52 to 57 which comprises
5 bioactive silicon.

59. The vehicle of any one of claims 47 to 51 which has associated
with it material to be transferred into a cell in a form adapted to
co-precipitate with a substance which is taken up by cells.
10

60. The vehicle of claim 59 wherein the co-precipitate is a calcium
phosphate co-precipitate.

61. A method of making a vehicle for transferring material into a cell
15 comprising the steps of rendering the vehicle at least partially porous and
introducing to it, or into it, the material to be transferred to the cell.

62. The method of claim 61 wherein the vehicle is a silicon bullet.

20 63. The method of claim 61 wherein the material to be transferred to
the cell is adhered to the vehicle.

64. The method of claim 63 wherein the vehicle is a submicron particle
and the material to be transferred to the cell is co-precipitated (with a
25 precipitate substance), using the vehicle as a nucleation site.

65. The method of claim 61 wherein the vehicle is impregnated with
the material to be transferred to the cell.

66. A method of electroporation comprising providing an electrically conducting bioactive silicon electrode.

5 67. A method according to claim 66 comprising growing cells on the electrode.

68. A method according to claim 66 or 67 comprising providing an array of bioactive silicon electrodes.

10 69. A method according to claim 68 comprising growing cells on the array.

70. Electroporation apparatus comprising a bioactive electrode.

15 71. Electroporation apparatus according to claim 70 in which the electrode comprises porous silicon.

72. Electroporation apparatus according to either of claims 70 or 71 having an array of electrodes, or microelectrodes.

20

73. A method of manufacturing the microneedle or microneedle array substantially as described herein with reference to Figure 2 or Figure 3 of the accompanying drawings.

25 74. A method of producing the micropiercing device substantially as described herein and with reference to Figure 1 of the accompanying drawings.

75. A cell penetration member substantially as described herein and with reference to Figure 1 or Figure 2 or Figure 3 of the accompanying drawings.

5 76. A vehicle for delivering material into a cell substantially as described herein with reference to Figure 4 or Figure 5 of the accompanying drawings.

10 77. A method of transferring material into a cell substantially as described herein with reference to Figure 4 or Figure 5 of the accompanying drawings.

15 78. A method of transferring material into a cell substantially as described herein with reference to Figure 6 of the accompanying drawings.

ABSTRACT

TRANSFERRING MATERIALS INTO CELLS AND A
MICRONEEDLE ARRAY

5

The present invention relates to the use of porous silicon in the delivery of substances into cells. The porous silicon can be formed into micropiercers, microneedles and biolistic bullets for penetration of the cell. The control of the pore size and porosity of the porous silicon
10 allows tuning of the bioactivity of the porous silicon. The porous silicon is also resorbable and is therefore resorbed from the cells without leaving any particles or being seen as a foreign body. The present invention also relates to the methods of manufacturing the porous silicon micropiercers, microneedles, microelectrodes, biolistic bullets, and precipitation of
15 calcium phosphate on a bioactive substrate, and their advantages over known methods of delivering materials into cells.

To be accompanied, when published, by Figure 1 of the accompanying drawings.
